

Spec-Driven Development in Action

Using AI to Turn Requirements into Tests and Code

Who trusts AI-generated code?

Raise your hand if you completely trust everything it generates.

That is exactly the problem we will solve today.

Use AI across the workflow

Most teams use AI only at the implement phase — or to generate a Jira ticket.

Today we use it throughout the entire workflow.

Not just better prompts — better constraints

Traditional AI

Less context. More guessing.

Spec-Driven AI

More context. Less guessing.

TaskFlow

Existing application

Today's feature

Password Reset

Cursor + specs/password-reset.md

specs/password-reset.md

technical design
acceptance criteria
test scenarios
implementation
change requirement

Why did it work?

**Better
requirements**

AI had enough context.

**Shared
understanding**

Product, QA and Engineering
aligned earlier.

**Controlled
AI output**

We constrained the solution path.

The quality improvement came from the workflow, not magic.

Spec → Plan → Implement → Harness

Feedback loops turn one-off AI output into a repeatable delivery system.

What teams should take away

Build better

80/20: planning before coding

TDD and smaller PRs

Discipline beats speed theatre

Quality gates after each step

Work better

DEV and QA work in parallel

Shared (updated) specs reduce rework

DORA and SPACE to assess

Retrospectives is key (Harness)

Use AI better

Reset conversations when they drift

Control beats vibe coding

Keep humans in the judgment loop

Create skills to automate routine

AI makes delivery faster only when your process can absorb the speed.

Thank you
